Automated ML-based tool for classification problems

<u>Aim:</u> Development of a comprehensive python script that will run (binary or multi-class) classification problems on any given input data matrix

Input matrix Format: Standard Feature(F) x Instance(I) matrix (.csv) file.

| | F1 | F2 | F3 | F4 | | Fm | Class |
|----|----|----|----|----|------|----|----------|
| I1 | | | | | | | Class1 |
| 12 | | | | | | | Class2 |
| 13 | | | | | | | Class3 |
| 14 | | | | | | | |
| 15 | | | | | | | |
| | | | | | | | |
| In | | | | | | | Class x, |
| | | | | | | | y, z |

The options for the following functions or subroutines will be asked from the user as standard input.

Rules:

- 1. Every script(s) will contain elements of an ideal machine learning pipeline
 - a. Normalization / standardization
 - b. Feature selection
 - c. Cross validation
 - d. Machine learning modeling (classification)
 - e. Predictive capability (accuracy) of the model will be validated using a blind dataset that can be 10% of the data which will be kept aside and will never be used for training or testing of the models.
 - f. All performance metrics will be reported for overall cross-validated sets.
- 2. Every step of the ML model will be in a separate python script which will be called through a main python script. Only this main python script will be used for execution.
- 3. Output of the scripts (plots, tables, printing) will be generated in the form of a .pdf file.
